## Deseriptions of New Henera and Species of Ilymenoptera firom India.

By P. Cameron.<br>(Continuation.)

The keel bounding the areola and the basal areae united to it is roundly narrowed in the middle, the two united forming one area, contracted in the middle; the keel bounding the apex of the lateral areae is received close to the apex of the areola. The anteunae are annulated with white. The post-petiole is dilated and clearly separated; the wings are hyaline or only slightly infuscated; the colour of the body is blue or dark blue. The genus has some affinity with Lareiga; that genus may be known from it by the spined median segment, by the abdomen being neither punctured nor striated and by the areola with the basal area not being narrowed in the centre. *)

To this genus belongs "Ichneumon" Goodwin-Austini Cam.

1. C. rufo-femorata, sp. nov. O. Nigra, abdominis apice coeruleo; orbitis oculorum, linea pronoti annuloque antennarum flavis; femoribus posticis rufis, alis Ingalinis, stignate nervisque nigris. - Long. 14 mm .

Hab. Simla (Nurse).
Head black, except for a white line on the outer orbits, opposite the front and another in the middle behind. Face and vertex rather strougly punctured; the punctures on the clypens are larger, deeper and more widely separated ; and it is covered thickly with white pubescence; its sides are pale testaceons; the foveae are large. Face roundly raised in the middle. Mandibles black, shiniug ; the base closely, the middle more sparsely, punctured ; the labial palpi black; the maxillary for the greater part white; both are thickly covered with white hair. Front and vertex strongly and closely punctured : the former with some transverse striae; the face is covered with white, the vertex with black, hair. Thorax black, except for an interrupted white line on the edge of the pronotum ; the tubercles, a small mark below them aud the scutellar

[^0]keels which are yellowish-white. Mesouotum and scutellum shining, covered with large, rather widely separated punctures; those on the scutellum are more widely apart than those on the mesonotum. Scutellum flat, uarrowed towards the apex : the post-seutellum closely punctured, except at the apex. The areola is wider than long, is obliquely uarrowed towards the base; the petiolar area becomes obliquely wider towards the base; where it is fully wider than the apex of the areola; it is aciculated and irregularly punctured; the areola is irregularly rugosely striated, more strongly in the middle than at the sides; the lateral areae are coarsely, rugosely punctured; the basal on the inner half is closely, finely obliquely striated; the posterior median area is closely rugosely punctured, the base more strongly than the apex. Proplenrae closely and strongly punctured; the lower part closely obliquely striated. Mesopleurae shining, distinetly, but not very closely, punctured; the base above impunctate. Metapleurae rugosely punctured; the base below the middle with some stout curved keels; the middle keels extend to the apex of the coxae. Mesosternum punctured like the mesoplenrae; the furrow is deep, not much widened beliud and bearing some stont trausverse keels. Legs black; the fore tibiae are white in front; the linder femora bright red, except at the apex. Abslomen black; the apical 4 segments iudigo-blue; the apex of the petiole is broadly raised in the middle and is strongly and closely longitudinally striated; the gastrocoeli are large and deep; their base with 7 stout, more or less oblique, keels; the part between them is stoutly longitudinally striated; the base of the 3 rd segment and of the 4 th, to a less extent, longitudinally striated. The 2 nd and 3 rd segments are closely punctured; the 4 th less strongly; the others are impunctate.

The autennae in the $O$ are stont, black; the 10 th to the 17 th joints are white beueath; they are covered with a white down. The wings are hyaline aud strongly iridiscent.

## 2. C. cocruleicaudis sp. nov. Q. Loug. 14 mm .

Ha b. Khasia (Coll. Rothuey).
Agrees closely with C. nigrocoerulea, but the blue color on the abdomen is only visible on the apical segments; the white colour on the iuner orbits dues not extend below the antemnae; the scutellum is much less strongly punctured; the areola is longer than broad, not broader thau long; the spiracular area is less closely striated aud the mandibles are not yellow at the base.

Head black, except for a white line ou the inuer orbits
oprosite the front and oue in the middle behind. The face and vertex are rather strongly puactured: the punctures on the elypens are larger, deeper and more widely separated and thickly covered with white pubescence; the face is roundly couvex above; the clypeal fovene large ; the sides of the clypeus are pale testaceous. Mardibles black, shining: the base closely. the centre more sparsely, punctured: the labial palpi blackish; the maxillary dark testaceous; both are thickly covered with white hair. Front and vertex strongly and closely punctured; the former with some transverse striations; the face covered with white, the vertex with haek, hair. Thorax black, except for an interrupted white line on the elge of the pronotum and a mark ou the middle of the scntellar keels; the mesonotum and scutellum shining; covered with large, rather widely separated, punctures; those on the sentellum being more widely apart. Scutellum flat, narrowed towards the apex; the post-scutellum closely punctured, except ou the apex. The base of the median segment is fiuely and closely transversely striated; the areola is slightly longer than broad; its hase slightly rounded, almost trausverse; the apex is romded inwardly : iuside it is rough, irregularly obliquely strintel; the posterior median area is closely rngosely reticulated; its top and sides stoutly striated; the striations becoming larger below; the outer areae are coarsely rugose and coarsely transversely striated below; the spiracular area transversely rugosely punctured, behind more elosely and not so strongly. Propleurae shining, closely behind, in the middle, stontly and sharply, striated; the mesopleurae shining, elosely, but not strongly, punctured; the metapleurae coarsely, rugosely punctured, the punctures ronning into striations behind. Mesosternum punctured like the pleurae; the central furrow deep, not much widened behind and bearing stout transverse keels throughout. Legs black; the hinder femora ferraginons, except at the apex ; the anterior tibiae and tarsi dirty testaceons. Wings fuscous-violaceous: the stigma and nervnres black; the areolet marrowed at the top, being there scarcely the length of the space bounded by the recurrent aud the second transverse cubital nervares; the recurrent nervure is received beyond the middle, almost at the base of the apical third of the cellnle, Petiole smooth; the apex in the middle strongly longitudinally striated; the second segment is closely punctured, the middle, at the base, stoutly and sharply striated; the gastrocoeli smooth, impunctate; on the iunerside, at the base, are 7 stout keels: the 3 rd segment is less strongly aurl closely punctured and at the base, in the middle, bears some short, longitudinal striations: the apex of the 4 th and the succeediug segments are cobalt-blue,

3, C. nigro-cocrulea sp. niov. Q. Nigra, abdomine coemuleo; femorilus posticis late rufis; annulo flagelli antennarum albo; alis fusco-violaceis; nervis stigmateque nigris. - Long. 15 mm ,

## Hab. Khasia (Coll. Rothney).

Antenmae black; the 10 th to 15 th joints white at the sides and beneath; the scape strongly punctured. Head thickly covered with soft white hair; the inner orbits uarrowly from near the hinder ocelli to opposite the base of the antenuae, a small mark, near the eyes, shortly behind the hinder ocelli; the sides of the clypens and a narrow line on the onter orbits uear the middle, yellow. Face and clypens strougly punctured; the punctures on the clypeus, especially near the apex, are longer and more widely separated; the mandibles at the base strongly punctured, broadly rufous in the front of the teeth; the palpi white, blackish at the base. Thorax black; thickly covered with short, fuscous hair; a narrow line on the pronotum, extending from close to the base to the tegulae: the outer elge of the tegulae; the base of the tubercles and of the scutellar keels and an interrupted line on the base of the pronotum, yellow. Mesonotun strongly and almost uniformly punctured ; the sentellum similarly punctured, but with the punctures more widely separated; especially behind; the postscitellum fincly and closely punctured. The base of the median segment flnely and closely obliquely striated laterally; the posterior median area at the base irregnlarly and closely transversely striated; its apex irregularly reticulated; the posterior median finely and somewhat irregularly striated; its sides with stout, distinetly separated keels, which become louger from the base to the apex of the area: the tooth-bearing area irregnlarly and strongly reticulated; the spiracular area at the base is punctured; the rest of it somewhat irregularly obliquely striated. Propleurae strongly punctured, the middle behind widely obliquely and strongly striolated. Mesopleurae strongly punctured, more closely above; the apex hollowed, its upper edge with a row of 6 large deep foveae, in front of which is a smooth space; the upper part of the metapleurae, at the base, finely and closely punctured, below which is a distinct hollow; the rest is strongly punctured; below the hollow are a few short striations, followed, lower down, by stouter keels, the central being the longer and stouter; and it is curved downwards at the apex, where those below become united to it. Legs thickly covered with short white hair; the apex of the fore femora and tibiae yellowish; the hinder coxae strongly punctured, yellowish at the apex behind; the posterior femora ferruginous, black at the apex. Wings fuscous-violaceous; the stigma
and nervures black: the areolet narrowed at the top, being there one half of the part bounded by the first transverse cubitai and the recurrent nervure ; which is received shortly beyond the middle of the cellule. Abdomen blue, with purple tinges; the petiole at the base closely, somewhat irregularly striated; the middle at the apex strongly longitudinally striolated; the sides at the apex with a few scattered panctures; the $2^{\text {nd }}$ segment closely and strongly punctured; its base with 6 stout keels extending to the middle of the segment, becoming thinner as they do so; the gastrocoeli large, deep; the base with stont longitudinal keels; the 3 rd segment closely punctured; the others smooth.

The $\delta^{7}$ has the antennae entirely black; the inner orbits from near the front ocellus; the sides of the clypens and a somewhat triangular mark on the base of the mandibles, yellow; otherwise as in the $O$, except that all the abdominal segments are strongly and closely punctured.

## 6. Lareiga, gen. nor.

Areola open behind, slightly longer than wide; all the other areae clearly scparated; the sides of the median segment with blunt teeth. Mesosternum with a curved wide furrow on either side at the base; the median segment toothed at the apex. Post-petiole slightly punctured in the middle; the other segments smooth and shining ; the last segment, above and below, as long as the penultimate; the ventral keel is large and extends to the apex of the 4 th segment. Gastrocoeli shallow. The upper tooth of the mandibles is much longer and more sharply pointed than the lower. Clypeal foveae large. The antenuae have the basal joints of the flagellum all longer than broad. Scutellum rather flat; its sides not keeled; post-scutellum deeply depressed laterally. Metathoracic spiracles long, narrow, curved. Areolet 5 -angled, narrowed at the top; the disco-cubital and the recurrent nervures have the stump of a nervure; the transverse median nervure is received distinctly in front of the transverse basal. Tarsi thickly spinose.

The antennae in the $\sigma^{7}$ are as long as the body and are serrate towards the apex. The head is roundly, obliquely narrowed behind; the occiput is roundly incised ; the apex of the median segment has an oblique slope; the post-petiole is not clearly separated, it gradually merging into the petiole ; in the $\sigma^{7}$ it is longer and narrower. There is a stont keel before the middle of the propleurae.

The distinctive characters of this genus are the areola.
longer than wide and open behind; the toothed median segment and the smooth, almost imponctate abdomen. The thorax in the known species is black, marked with yellow; the abdomen metallic blue; and the tibiae aud tarsi are marked with white.

1. rufofemorata, sp. nor. Q. Nigra; abdomine coernleo; anmulo flagelli antennarum, coxis trochanteribusque anteriorilins, tiliurum basi late, facie, linea pronoti, tegntis allis; alis hyalinis, nerris nigris. - Long. 13 mm .

Hab. Khasia (Coll. Rothney).
Antennae black; the 10 th -18 th joints white beneath ; the scape rufons. Head black; the face and clypeus rufous, darker in the middle; the upper side of the face next to the eyes and the upper side of the clypens near the foveae, gellow ; the lower orbits on the inner side, narrowed below, dilated in the middle to near the lower ocellus and narrowed again to near the middle and the lower part below, broadly yellow. Face and clypens closely and strongly punctured; the vertex smooth; the front finely punctured below the ocelli. Maudibles black, rufous at the base and before the teetl; the middle punctured. Thorax black, the edge of the pronotum narrowly behind, and broader at the apex; the tubercles, tegulae, the sentellum and post-scutellum, yellow. Mesonotum almost opaque and closely punctured. Scutellum smooth. Proplewrae smooth, the hinder elge, except at the top, longitudinally striated ; the striae small above, coarser below. Metapleurate longitudinally striated, finely above, coarsely below. Median segment finely and closely transversely striated; the areola is a little longer than wide; the lateral keels bulje roundly outwardly; the teeth are large and stout. Legs rufous; the fonr anterior and the apex of the hinder coxae; the base of the tibiae broadly and the middle of the tarsi broadly, white; the base of the tibiae slightly and of their apex broadly, black; the metatarsus and the apex of the terminal joint, black. Areolet oblique, narrowed at the top; the width there being not mueh more than the space bounded by the recurrent and the 2 nd transverse cubital nervures; the recurrent nervure is received shortly beyond the middle of the cellule. Petiole smooth, impunctate ; the gastrocoeli shallow, indistinet; the base finely striated; the 2nd segment finely pmetured ; the others almost impunetate.

The $\sigma^{2}$ has the face and clypens entirely yellow; the seape of the antemnae is yellow beneath; on the base of the mesoplenrae, at its junction with the sternum, is a somewhat triangular yellow mark.

## \%. Belargea, gen. nor.

Areola separated, twice broader than long. Sides of median segment stontly spined. Face flat. Apex of clypens transverse; its sides not romded. Head obliquely narrowed behind ; the occiput roundly, deeply incised and sharply margined. Scutellum ronndly convex, but not much raised; its sides not keeled. Areolet 5 -angled, wide at te top; the discocubital nervure has the stump of a nervure; the transverse basal nervure is interstitial. Tarsi long, spinose; the apex of the hinder femora reach near to the apex of the 4 th abdominal segment. The 2nd and the base of the 3rd segments are closely punctured; the gastrocoeli are narrow and dilated at the apex.

The median segment is completely areolated. The npper tooth of the mandibles is large, narrowed and romded at the apex; the lower is shorter and obliquely bent inwardly. The depression at the base of the median segment is wider at the base than the areola and has an oblique slope.

This genus resembles in its main features Laveiga. The two may be separated by the radical difference in the form of the areola: in Lareiga it is twice longer than broad and is open behind; in the present genus it is twice broader than long and is closed by a keel at the base. The gastrocoeli are more distiuct than in Lareiga.
B. allomaculata, sp. nor. Q. Nigra; abdomine coeruleo, mesonoto mesopleurisque albo-maculatis; pedibus rufis; coxis, trochunteribus, dimidio basali tilvarum posticurum albis; alis hyalinis, stigmate nervisque nigris. -- Long. 16 mm .

Hab. Khasia Hills. (Coll. Rothney).
Scape of auteunae yellowish beneath; the flagellum somewhat brownish. Head black; the face, clypeus, labrum, palpi, the imuer eye orbits above - the band triangularly dilated in the middle - and the outer - narrowly above, broadly below -, yellow. Face and clypeus punctured and closely covered with white hair ; the face more closely punctured and with the hair shorter than on the clypeus. Mandibles black; the base with a yellow mark on the top above and thickly covered with pale fulvous hair. Occipnt sharply margined ; the vertex impunctate, the front smooth and shining. On the thorax there is a broad line on the pronotum, a mark, broader than loug, on the hinder part of the mesonotim in the middle $e_{\text {; }}$ the scutellum, post-scutellum, except in the middle, and a large oblique mark on the lower side of the mesopleurae at
the base, yellow. Mesonotum opaque, thickly covered with short pubescence and closely punctured. Scatellum smooth, covered with long pale hair, longer thau broad, rounded at the base and narrowed gradually towards the apex. On the median segment the areola is smooth and shining, rounded outwardly at the base, iuwardly at the apex : it is distinctly wider than long; the basal areae are aciculated; the apical closely trausversely striated; the outer more strongly than the mediau; the base of the spiracular area strougly aciculated; the middle closely, the apical part coarsely, transversely striated. Propleurae aciculated, the apex striated. Mesopleurae bearing shallow punctures; the base, the upper part and the middle striated. Mesosteruum closely punctured; its central furrow widely and deeply depressed at the apex. The 4 anterior coxae, aud their trochanters are yellow, the hinder black. except the coxae which are broadly yellow at the apex and more narrowly below; the femora rufous, black at the apex above; the 4 anterior are more or less yellowish in front; the 4 front tibiae rufous, yellowish in front; the anterior narrowly at the base, broadly at the apex, the middle in part yellow; the hinder tarsi have the basal and apical joints black; the others dull rufous. Wings fulvo-hyaline, the nervores and stigma black; the areolet at the top slightly less in length than the space bounded by the recurrent and the transverse cubital nervures; the recurrent nervure is received near the middle. The abdominal petiole is of a darker blue than the rest of the abdomen; it is shining; its middle, except at the apex, with large, deep punctures; the gastrocoeli are smooth in the middle, their apex fulvons.

## 8. Odontojoppa gen. nor.

Areola large, twice longer than wide, open behind, its apex reaching to the top of the truncation; the lateral areae are not clearly separated and are only two in namber; the sides of the segment bear stout, broad spines. Labrum projecting. Clypeus not distiuctly separated from the face. Scutellum roundly convex; its sides not margined. The sides of the mesosternum have a broad shallow furrow at the base. Areolet 5 -angled, narrowed at the top; the transverse basal nervure is interstitial; the disco-cubital and the recurrent nervures bear short branches. Legs moderate in length; the apex of the hinder femora reaches to the apex of the 3 rd segment; the tarsi are long and spinose.
(Continuation follows.)
